1 Countability: True or False

Note 11 (a) The set of all irrational numbers $\mathbb{R}\setminus\mathbb{Q}$ (i.e. real numbers that are not rational) is uncountable.

- (b) The set of integers x that solve the equation $3x \equiv 2 \pmod{10}$ is countably infinite.
- (c) The set of real solutions for the equation x + y = 1 is countable.

For any two functions $f: Y \to Z$ and $g: X \to Y$, let their composition $f \circ g: X \to Z$ be given by $(f \circ g)(x) = f(g(x))$ for all $x \in X$. Determine if the following statements are true or false.

- (d) f and g are injective (one-to-one) $\implies f \circ g$ is injective (one-to-one).
- (e) f is surjective (onto) $\implies f \circ g$ is surjective (onto).

Solution:

- (a) **True.** Proof by contradiction. Suppose the set of irrationals is countable. From Lecture note 10 we know that the set \mathbb{Q} is countable. Since union of two countable sets is countable, this would imply that the set \mathbb{R} is countable. But again from Lecture note 10 we know that this is not true. Contradiction!
- (b) True. Multiplying both sides of the modular equation by 7 (the multiplicative inverse of 3 with respect to 10) we get x ≡ 4 (mod 10). The set of all intergers that solve this is S = {10k+4 : k ∈ Z} and it is clear that the mapping k ∈ Z to 10k+4 ∈ S is a bijection. Since the set Z is countably infinite, the set S is also countably infinite.
- (c) False. Let S ⊂ ℝ × ℝ denote the set of all real solutions for the given equation. For any x' ∈ ℝ, the pair (x', y') ∈ S if and only if y' = 1 − x'. Thus S = {(x, 1 − x) : x ∈ ℝ}. Besides, the mapping x to (x, 1 − x) is a bijection from ℝ to S. Since ℝ is uncountable, we have that S is uncountable too.
- (d) True. Recall that a function h: A → B is injective iff a₁ ≠ a₂ ⇒ h(a₁) ≠ h(a₂) for all a₁, a₂ ∈ A. Let x₁, x₂ ∈ X be arbitrary such that x₁ ≠ x₂. Since g is injective, we have g(x₁) ≠ g(x₂). Now, since f is injective, we have f(g(x₁)) ≠ f(g(x₂)). Hence f ∘ g is injective.
- (e) **False.** Recall that a function $h : A \to B$ is surjective iff $\forall b \in B, \exists a \in A$ such that h(a) = b. Let $g : \{0,1\} \to \{0,1\}$ be given by g(0) = g(1) = 0. Let $f : \{0,1\} \to \{0,1\}$ be given by f(0) = 0 and f(1) = 1. Then $f \circ g : \{0,1\} \to \{0,1\}$ is given by $(f \circ g)(0) = (f \circ g)(1) = 0$. Here f is surjective but $f \circ g$ is not surjective.

2 Counting Cartesian Products

Note 11 For two sets *A* and *B*, define the cartesian product as $A \times B = \{(a, b) : a \in A, b \in B\}$.

- (a) Given two countable sets A and B, prove that $A \times B$ is countable.
- (b) Given a finite number of countable sets A_1, A_2, \ldots, A_n , prove that

$$A_1 \times A_2 \times \cdots \times A_n$$

is countable.

(c) Consider a countably infinite number of finite sets: $B_1, B_2, ...$ for which each set has at least 2 elements. Prove that $B_1 \times B_2 \times \cdots$ is uncountable.

Solution:

- (a) As shown in lecture, $\mathbb{N} \times \mathbb{N}$ is countable by creating a zigzag map that enumerates through the pairs: $(0,0), (1,0), (0,1), (2,0), (1,1), \ldots$ Since *A* and *B* are both countable, there exists a bijection between each set and a subset of \mathbb{N} . Thus we know that $A \times B$ is countable because there is a bijection between a subset of $\mathbb{N} \times \mathbb{N}$ and $A \times B : f(i, j) = (A_i, B_j)$. We can enumerate the pairs (a, b) similarly.
- (b) Proceed by induction.

Base Case: n = 2. We showed in part (a) that $A_1 \times A_2$ is countable since both A_1 and A_2 are countable. Induction Hypothesis: Assume that for some $n \in \mathbb{N}$, $A_1 \times A_2$ is countable.

Induction Hypothesis: Assume that for some $n \in \mathbb{N}$, $A_1 \times A_2 \times \cdots \times A_n$ is countable.

Induction Step: Consider $A_1 \times \cdots \times A_n \times A_{n+1}$. We know from our hypothesis that $A_1 \times \cdots \times A_n$ is countable, call it $C = A_1 \times \cdots \times A_n$. We proved in part (a) that since *C* is countable and A_{n+1} are countable, $C \times A_{n+1}$ is countable, which proves our claim.

(c) Let us assume that each B_i has size 2. If any of the sizes are greater than 2, that would only make the cartesian product larger. Notice that this is equivalent to the set of infinite length binary strings, which was proven to be uncountable in the notes.

Alternatively, we could provide a diagonalization argument: Assuming for the sake of contradiction that $B_1 \times B_2 \times \cdots$ is countable and its elements can be enumerated in a list:

$$(b_{1,1}, b_{2,1}, b_{3,1}, b_{4,1}, \dots)$$
$$(b_{1,2}, b_{2,2}, b_{3,2}, b_{4,2}, \dots)$$
$$(b_{1,3}, b_{2,3}, b_{3,3}, b_{4,3}, \dots)$$
$$(b_{1,4}, b_{2,4}, b_{3,4}, b_{4,4}, \dots)$$
$$\vdots$$

where $b_{i,j}$ represents the item from set B_i that is included in the *j*th element of the Cartesian Product. Now consider the element $(\overline{b_{1,1}}, \overline{b_{2,2}}, \overline{b_{3,3}}, \overline{b_{4,4}}, \dots)$, where $\overline{b_{i,j}}$ represents any item

from set B_i that differs from $b_{i,j}$ (i.e. any other element in the set). This is a valid element that should exist in the Cartesian Product B_1, B_2, \ldots , yet it is not in the enumerated list. This is a contradiction, so $B_1 \times B_2 \times \cdots$ must be uncountable.

3 Hello World!

- Note 12 Determine the computability of the following tasks. If it's not computable, write a reduction or self-reference proof. If it is, write the program.
 - (a) You want to determine whether a program P on input x prints "Hello World!". Is there a computer program that can perform this task? Justify your answer.
 - (b) You want to determine whether a program *P* prints "Hello World!" before running the *k*th line in the program. Is there a computer program that can perform this task? Justify your answer.
 - (c) You want to determine whether a program P prints "Hello World!" in the first k steps of its execution. Is there a computer program that can perform this task? Justify your answer.

Solution:

(a) Uncomputable. We will reduce TestHalt to PrintsHW(P, x).

```
TestHalt(P, x):
 P'(x):
  run P(x) while suppressing print statements
  print("Hello World!")
 if PrintsHW(P', x):
  return true
 else:
  return false
```

If PrintsHW exists, TestHalt must also exist by this reduction. Since TestHalt cannot exist, PrintsHW cannot exist.

(b) Uncomputable. Reduce PrintsHW(P,x) from part (a) to this program PrintsHWByK(P,x,k).

```
PrintsHW(P, x):
for i in range(len(P)):
  if PrintsHWByK(P, x, i):
     return true
return false
```

(c) Computable. You can simply run the program until *k* steps are executed. If *P* has printed "Hello World!" by then, return true. Else, return false.

The reason that part (b) is uncomputable while part (c) is computable is that it's not possible to determine if we ever execute a specific line because this depends on the logic of the program, but the number of computer instructions can be counted.
