1 Extended Euclid: Two Ways

In this problem, we will explore the Extended Euclid’s Algorithm: first, the traditional implementation, and second, a faster, iterative version. Both ways yield the same result.

Parts (b) and (c) explore the traditional Extended Euclid’s Algorithm. The bolded numbers below keep track of which numbers appeared as inputs to the gcd call. Remember that we are interested in writing the GCD as a linear combination of the original inputs, so we don’t want to accidentally simplify the expressions and eliminate the inputs.

(a) As motivation, suppose we’ve found values of \( a \) and \( b \) such that \( 54a + 17b = 1 \). With this knowledge, what is \( 17^{-1} \pmod{54} \)?

(b) Note that \( x \mod y \), by definition, is always \( x \) minus a multiple of \( y \). So, in the execution of Euclid’s algorithm, each newly introduced value can always be expressed as a "combination" of the previous two, like so:

\[
\begin{align*}
gcd(54, 17) &= gcd(17, 3) \\
&= gcd(3, 2) \\
&= gcd(2, 1) \\
&= gcd(1, 0) \\
&= 1.
\end{align*}
\]

(Fill in the blanks)

(c) Recall that our goal is to fill out the blanks in

\[
1 = \underline{\quad} \times 54 + \underline{\quad} \times 17.
\]

To do so, we work back up from the bottom, and express the gcd above as a combination of the two arguments on each of the previous lines:

\[
\begin{align*}
1 &= \underline{\quad} \times 3 + \underline{\quad} \times 2 \\
&= \underline{\quad} \times 17 + \underline{\quad} \times 3 \\
&= \underline{\quad} \times 54 + \underline{\quad} \times 17
\end{align*}
\]

What does this imply, in this case, about the multiplicative inverse of 17, in arithmetic \( \pmod{54} \)?
(d) In the previous parts, we used a recursive method to write \( \gcd(54, 17) \) as a linear combination of 54 and 17. We can also compute the same result iteratively—this is an alternative to the above method that is oftentimes faster. We begin by writing equations for our initial arguments, 54 and 17, as a linear combination of themselves:

\[
\begin{align*}
54 &= 1 \times 54 + 0 \times 17 \quad (E_1) \\
17 &= 0 \times 54 + 1 \times 17 \quad (E_2)
\end{align*}
\]

We can then use these initial equations (labeled \( E_1 \) and \( E_2 \) for ease of reference) to iteratively write reduced values as linear combinations of 54 and 17, until we are able to write an equation for \( \gcd(54, 17) \), as desired.

In particular, we want to subtract as many multiples of the second equation as possible from the first to create a new equation with a lower LHS value. We can keep iterating until the LHS becomes \( \gcd(54, 17) = 1 \).

\[
\begin{align*}
\phantom{=} &= \phantom{=} \times 54 + \phantom{=} \times 17 \quad (E_3 = E_1 - \phantom{=} \times E_2) \\
\phantom{=} &= \phantom{=} \times 54 + \phantom{=} \times 17 \quad (E_4 = E_2 - \phantom{=} \times E_3) \\
1 &= \phantom{=} \times 54 + \phantom{=} \times 17 \quad (E_5 = E_3 - \phantom{=} \times E_4)
\end{align*}
\]

What does this imply, in this case, about the multiplicative inverse of 17, in arithmetic mod 54? Verify that your answer is equivalent to the previous part.

(e) Calculate the \( \gcd \) of 17 and 39, and determine how to express this as a “combination” of 17 and 39. What does this imply, in this case, about the multiplicative inverse of 17, in arithmetic mod 39?
2  Chinese Remainder Theorem Practice

In this question, you will solve for a natural number \( x \) such that,
\[
\begin{align*}
    x &\equiv 1 \pmod{3} \\
    x &\equiv 3 \pmod{7} \\
    x &\equiv 4 \pmod{11}
\end{align*}
\]

(1)

(a) Suppose you find 3 natural numbers \( a, b, c \) that satisfy the following properties:
\[
\begin{align*}
    a &\equiv 1 \pmod{3} ; a \equiv 0 \pmod{7} ; a \equiv 0 \pmod{11}, \quad (2) \\
    b &\equiv 0 \pmod{3} ; b \equiv 1 \pmod{7} ; b \equiv 0 \pmod{11}, \quad (3) \\
    c &\equiv 0 \pmod{3} ; c \equiv 0 \pmod{7} ; c \equiv 1 \pmod{11}. \quad (4)
\end{align*}
\]

Show how you can use the knowledge of \( a, b \) and \( c \) to compute an \( x \) that satisfies (1).

In the following parts, you will compute natural numbers \( a, b \) and \( c \) that satisfy the above 3 conditions and use them to find an \( x \) that satisfies (1).

(b) Find a natural number \( a \) that satisfies (2). That is, \( a \equiv 1 \pmod{3} \) and is a multiple of 7 and 11.

It may help to start with a number that is a multiple of both 7 and 11; what number should we multiply this by in order to make it equivalent to 1 \( \pmod{3} \)?

(c) Find a natural number \( b \) that satisfies (3). That is, \( b \equiv 1 \pmod{7} \) and is a multiple of 3 and 11.

(d) Find a natural number \( c \) that satisfies (4). That is, \( c \equiv 1 \pmod{11} \) and is a multiple of 3 and 7.
(e) Putting together your answers for parts (a), (b), (c) and (d), report an \( x \) that satisfies (1).

3 Baby Fermat

Assume that \( a \) does have a multiplicative inverse mod \( m \). Let us prove that its multiplicative inverse can be written as \( a^k \pmod{m} \) for some \( k \geq 0 \).

(a) Consider the infinite sequence \( a, a^2, a^3, \ldots \pmod{m} \). Prove that this sequence has repetitions. 
   (\textbf{Hint:} Consider the Pigeonhole Principle.)

(b) Assuming that \( a^i \equiv a^j \pmod{m} \), where \( i > j \), what is the value of \( a^{i-j} \pmod{m} \)?

(c) Prove that the multiplicative inverse can be written as \( a^k \pmod{m} \). What is \( k \) in terms of \( i \) and \( j \)?
